Historical background of Antimicrobial Resistance to Neisseria gonorrhoeae:

- **1930s:** Introduction of sulfonamide antimicrobials to treat GC
- **1940s:** Due to increasing resistance, sulfonamides no longer recommended for GC treatment; penicillin becomes treatment of choice
- **1950s:**
- **1960s:**
- **1970s:**
- **1980s:** Due to increasing resistance, penicillin and tetracycline no longer recommended to treat GC
- **1990s:** Fluoroquinolones become predominant treatment
- **2000s:**
- **2010s:** Cefixime no longer recommended as first-line regimen, leaving ceftriaxone-based dual treatment as last recommended treatment
- **2015s:** Ceftriaxone plus azithromycin is the only recommended treatment for treating GC

- Research shows that continued rise in AMR could lead to 10 million deaths every year and a 3% reduction in GDP by 2050 (CDC, 2018)
New interventions to prevent community spread of MDR NG strains

• Surveillance is proposed as one of the intervention strategies to prevent community spread (Lee, 2013; WHO, 2014; CDC, 2018; Bett, 2019)

• Objective of the study was therefore to assess surveillance capacity for AMR NG strains in public hospitals within Kisumu County, Kenya

HOWEVER

• Capacity of laboratories as surveillance sites for NG testing is not well known in Kenya
Materials and methods

• Cross-sectional data from public hospitals in Kisumu County

• Hospitals classified as Kenya Essential Package for Health (KEPH) levels IV and above.

• 25 facilities qualified (Kisumu County Health Reports, 2018)

• 12 (48%) randomly selected facilities after being assessed for availability of:
  o STI related services
  o Laboratories that can perform basic microbiology
  o Data management system

• Data was collected using:
  o Questionnaires
  o Laboratory report forms
  o Direct observations
  o Check lists and
  o Desk review forms
Results

50% of the facilities had <6 essential equipment for diagnosing NG (n=11)

91.7% of the facilities lacked biological wire loop & magnetic stirrer (n=12)

Urban hospitals had 36.4% of the essential equipment compared to 18.2% in rural hospitals (n=11)
Results (contd)

All the study sites lacked 56.3% of consumables essential for diagnosing NG (n=16)

91.7% of the study sites lacked capacity to perform NG culture and susceptibility testing (n=12)
Discussions & Conclusions

Discussions:
• All the 12 (100%) hospitals reported having qualified laboratory staff

• Only KEPH Level V hospital laboratory showed some capacity to perform bacterial culture and AMS testing (phenotyping), but not AMR testing (genotyping).

• However, the hospital could not isolate NG due to lack of some essential equipment and consumables.

Conclusions:
• These results should enable the government to identify hospitals whose capacities can be built faster, with less capital for initiation of antimicrobial resistance surveillance, in order to help reduce emergence and community transmission of multi-drug resistant NG strains for effective drug choices in Kenya.
Recommendations

• Qualified laboratory staff should undergo mandatory continuous professional development (CPD) for efficient surveillance studies.

• At least one KEPH level V public hospital should be well equipped, in every county, to act as dedicated sentinel surveillance site in Kenya.

• Sentinel surveillance can be facilitated by selection of KEPH level IV hospitals meeting minimum requirements for sample flow.

• Ongoing surveillance is required to reveal community transmission patterns of MDR organisms.
